

**APPENDIX E**  
**REVISED SECTION 2.4.6.10.9**

#### **2.4.6.10.9 Vector Control**

Proper daily covering of the waste should eliminate problems with insect and mammal pests. Prompt clean-up of blowing papers, debris and wind screens will minimize exposure of this material for vectors. Stationary wind fence will be installed in working areas and will be periodically moved as the active work areas are moved. Temporary wind fencing and screens will also be used at working areas, as required. Other litter control measures were discussed previously in Section 2.4.6.10.6 . Vectors are greatly discouraged when waste materials are not easily available.

The site is designed and will be operated in a manner which minimizes ponding or other standing water on the landfill area, and this will eliminate potential breeding grounds for flies, mosquitoes and other insects.

Should vector control present a problem at the site, cover soil use can be increased, or an extermination program could be initiated. Any extermination program would be developed in strict accordance with the requirements of the NYSDOH and the NYSDEC.

Additional discussion of vector control measures is presented in the O&M Manual for the currently permitted SMI operations. Similar procedures will be utilized in connection with the proposed Landfill Expansion.
